Multiple Regression with Factor Predictors

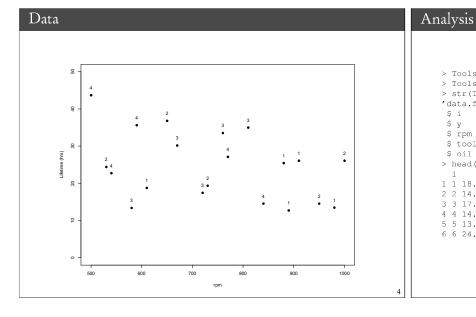

Example: Tool lifetime data

20 observations of machine tools operating lifetimes:

- x_{i1} operating speed (rpm): continuous;
- x_{i2} tool type (tool):
 - ▶ factor predictor,
 - $M_2 = 2$ levels (Type: A, B);
- x_{i3} oil type (oil):
 - ► factor predictor,
 - $M_3 = 4$ levels (Type: 1, 2, 3, 4);
- y_i lifetime in hours, outcome.

```
> Tools<-read.csv('Tools.csv')
> Tools$oil<-as.factor(Tools$oil)
> str(Tools)
'data.frame': 20 obs. of 5 variables:
$ i : int 1 2 3 4 5 6 7 8 9 10 ...
$ y : num 18.7 14.5 17.4 14.5 13.4 ...
$ rpm : int 610 950 720 840 980 530 580 540 890 730 ...
$ tool: Factor w/ 2 levels "A", "B": 1 1 1 1 1 1 1 1 1 1 1 ...
$ oil: Factor w/ 4 levels "1", "2", "3", "4": 1 2 3 4 1 2 3 4 1 2 ...
> head(Tools)
i y rpm tool oil
1 1 18.73 610 A 1
2 2 14.52 950 A 2
3 3 17.43 720 A 3
4 4 14.54 840 A 4
5 5 13.44 980 A 1
6 6 24.39 530 A 2
```

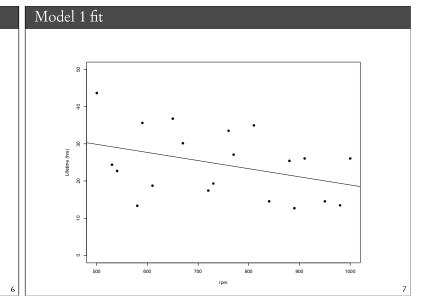

Analysis

Fit Model 1:

$$Y_i = \beta_0 + \beta_1 x_{i1} + \epsilon_i$$

or X_1 , or rpm.

Residual standard error: 8.654 on 18 degrees of freedom Multiple R-squared: 0.1441, Adjusted R-squared: 0.09659 F-statistic: 3.031 on 1 and 18 DF, p-value: 0.09873

Model 2

Fit Model 2:

$$X_1 + X_2$$

that is,

$$Y_i = eta_{ extsf{0}} + eta_1 x_{i1} + \sum_{j=1}^{M_2-1} eta_{2j}^{ extsf{C}} \mathbb{1}_j(x_{i2}) + \epsilon_i$$

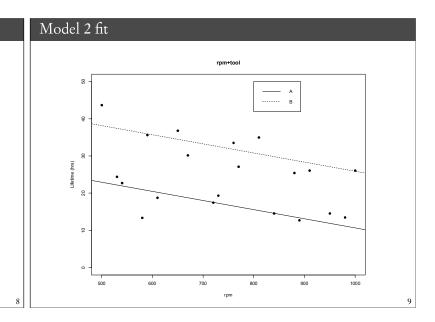

or rpm+tool.

```
> fit2<-lm(y~rpm+tool,data=Tools)
> summary(fit2)
Coefficients:
```

| Estimate Std. Error t value Pr(>|t|) | (Intercept) 35.208726 3.738882 9.417 3.71e-08 *** rpm -0.024557 0.004865 -5.048 9.92e-05 *** toolB 15.235474 1.501220 10.149 1.25e-08 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 3.352 on 17 degrees of freedom Multiple R-squared: 0.8787, Adjusted R-squared: 0.8645 F-statistic: 61.6 on 2 and 17 DF, p-value: 1.627e-08

Model 2

In this case, the factor predictors has $M_2 = 2$ levels, to there is only one non-baseline group. In R, the default action sets the baseline group by considering the factor level names alphabetically; here level A is the baseline group.

$$\mathbb{E}_{Y_i|X_i}[Y_i|\mathbf{x}_i] = \begin{cases} \beta_0 + \beta_1 x_{i1} & x_{i2} = 0 \text{ (Type A)} \\ \beta_0 + \beta_1 x_{i1} + \beta_{21}^{\text{C}} & x_{i2} = 1 \text{ (Type B)} \end{cases}$$

The parameter $\beta_{21}^{\mathbb{C}}$ measures the difference in the intercept between the Type A and Type B tools.

The estimate is $\widehat{\beta}_{21}^{\rm C}=$ 15.235 (line 36); the associated *t*-test of the null hypothesis

$$H_0: \beta_{21}^{C} = 0$$

reveals that the hypothesis is rejected (line 35, p-value 1.25e-08).

Comparing Model 2 to Model 1

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

In terms of single term deletions, we see that if either term is omitted from the model rpm+tool $(X_1 + X_2)$, then the test statistic is highly significant.

- Line 50: compares the model rpm+tool $(X_1 + X_2)$ with the model tool (X_2) , and tests the hypothesis $H_0: \beta_1 = 0$; this hypothesis is rejected $(p = 9.917 \times 10^{-5})$.
- Line 51: compares the model rpm+tool $(X_1 + X_2)$ with the model rpm (X_1) , and tests the hypothesis $H_0: \beta_{21}^c = 0$; this hypothesis is rejected $(p = 1.246 \times 10^{-8})$.

Comparing Model 2 to Model 1

Comparing Model 2 to Model 1 (cont.)

Partial *F*-tests reveal the same conclusions:

- Line 54: adds rpm (X_1) first, then tool (X_2)
- Line 65: adds tool (X_2) first, then rpm (X_1)

Note that the sequence of adding terms makes a difference to the sums of squares terms and the significance test results; lines 59 and 60 give the decomposition

$$\overline{SS}_R(\beta_1,\beta_{21}^{\scriptscriptstyle C}|\beta_0) = \overline{SS}_R(\beta_1|\beta_0) + \overline{SS}_R(\beta_{21}^{\scriptscriptstyle C}|\beta_0,\beta_1)$$

whereas lines 70 and 71 give the decomposition

$$\overline{SS}_{R}(\beta_{1},\beta_{21}^{C}|\beta_{0}) = \overline{SS}_{R}(\beta_{21}^{C}|\beta_{0}) + \overline{SS}_{R}(\beta_{1}|\beta_{0},\beta_{21}^{C})$$

We conclude that both predictors are helpful in predicting the response.

13

15

Model 3

Fit Model 3:

$$X_1 + X_2 + X_1 : X_2$$

that is,

$$Y_i = \beta_{\texttt{O}} + \beta_{\texttt{I}} x_{i1} + \sum_{j=1}^{M_2-1} \beta_{2j}^{\texttt{C}} \mathbb{1}_j(x_{i2}) + \sum_{j=1}^{M_2-1} \beta_{12j}^{\texttt{C}} x_{i1} \mathbb{1}_j(x_{i2}) + \epsilon_i$$

or

rpm+tool+rpm:tool.

In R, this model can also be specified as

rpm*tool

Model 3 (cont.)

```
> fit3<-lm(y~rpm+tool+rpm:tool,data=Tools)
> summary(fit3)
```

> summary(fit3

Coefficients:

Residual standard error: 3.201 on 16 degrees of freedom Multiple R-squared: 0.8959, Adjusted R-squared: 0.8764 F-statistic: 45.92 on 3 and 16 DF, p-value: 4.37e-08

14

12

Model 3 (cont.)

The model fitted here is

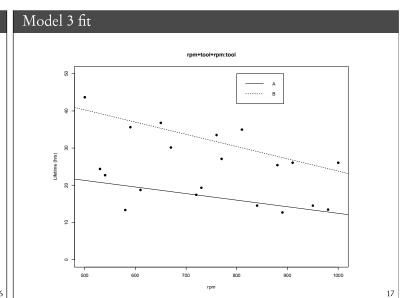

$$\mathbb{E}_{Y_i|X_i}[Y_i|\mathbf{x}_i] = \begin{cases} \beta_0 + \beta_1 x_{i1} & x_{i2} = 0 \text{ (Type A)} \\ \beta_0 + \beta_1 x_{i1} + \beta_{21}^{\text{C}} + \beta_{121}^{\text{C}} x_{i1} & x_{i2} = 1 \text{ (Type B)} \end{cases}$$

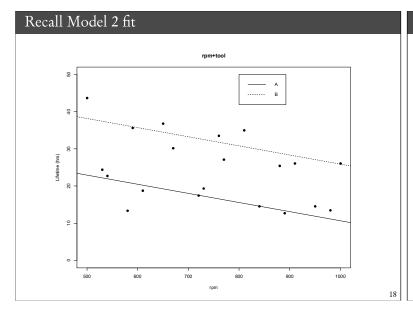

- The parameter β^c₂₁ measures the difference in the intercept between the Type A and Type B tools.
- The parameter β_{121}^{c} measures the difference in the **slope** between the Type A and Type B tools.

Lines 79 - 82 give inference and testing details for

$$\beta_0, \beta_1, \beta_{21}^{\rm C}, \beta_{121}^{\rm C}$$

respectively.

Comparing Model 3 to Model 2

The only single term deletion that is considered is the interaction term rpm:tool; the null hypothesis is

$$H_0 : \beta_{121}^C = 0$$

that is, whether there is a change in slope between the two groups.

19

Comparing Model 3 to Model 2 (cont.)

The test being carried out is a standard *F*-test using the test statistic

$$F = \frac{(SS_{Res}(Model\ 2) - SS_{Res}(Model\ 3))/r}{SS_{Res}(Model\ 3)/(n-p)}$$

where here

- r = 1 (the number of parameters set to zero by the null hypothesis)
- n p = n 4, as there are four parameters in Model 3.

Line 96 reveals that this null hypothesis is not rejected (p = 0.1235).

Comparing Model 3 to Model 2 (cont.)

22

20

Model 4 (cont.)

The model fitted for $\mathbb{E}_{Y_i|X_i}[Y_i|\mathbf{x}_i]$ is

$$\beta_0 + \beta_1 x_{i1}$$
 $x_{i2} = 0, x_{i3} = 0$ (Type A, Oil 1)
 $\beta_0 + \beta_1 x_{i1} + \beta_{31}^{C}$ $x_{i2} = 0, x_{i3} = 1$ (Type A, Oil 2)

$$\beta_0 + \beta_1 x_{i1} + \beta_{32}^{C}$$
 $x_{i2} = 0, x_{i3} = 2$ (Type A, Oil 3)

$$\beta_0 + \beta_1 x_{i1} + \beta_{33}^{C}$$
 $x_{i2} = 0, x_{i3} = 3$ (Type A, Oil 4)

$$\beta_0 + \beta_1 x_{i1} + \beta_{21}^{\text{C}}$$
 $x_{i2} = 1, x_{i3} = 0$ (Type B, Oil 1)

$$\beta_0 + \beta_1 x_{i1} + \beta_{21}^{C} + \beta_{31}^{C}$$
 $x_{i2} = 1, x_{i3} = 1$ (Type B, Oil 2)

$$\beta_0 + \beta_1 x_{i1} + \beta_{21}^{C} + \beta_{32}^{C}$$
 $x_{i2} = 1, x_{i3} = 2$ (Type B, Oil 3)

$$\beta_0 + \beta_1 x_{i1} + \beta_{21}^{C} + \beta_{33}^{C}$$
 $x_{i2} = 1, x_{i3} = 3$ (Type B, Oil 4)

There are eight subgroups of data defined by the $M_2 \times M_3 = 2 \times 4$ combinations of factor levels. There are six parameters in total, including the intercept β_0 .

Model 4 (cont.)

The dependence on continuous predictor X_1 is the same in all subgroups, that is, the slope is the same.

- The parameter $\beta_{21}^{\rm C}$ measures the difference in the **intercept** between the Type A and Type B tools, for every Oil type.
- The parameters $\beta_{31}^{\rm C}$, $\beta_{33}^{\rm C}$, $\beta_{33}^{\rm C}$ measure the difference in the intercepts between Oil Types 2, 3 and 4 and Oil Type 1.

Lines 121 - 126 give inference and testing details for

$$\beta_0, \beta_1, \beta_{21}^{\text{C}}, \beta_{31}^{\text{C}}, \beta_{32}^{\text{C}}, \beta_{33}^{\text{C}}$$

respectively.

24

25

Comparing Model 4 with Model 2

> anova(fit2,fit4) Analysis of Variance Table

17 190.98 14 161.21 3 29.766 0.8616 0.4838

The comparison between models

rpm+tool+oil

and

rpm+tool

is a test of the null hypothesis

$$H_0: \beta_{31}^C = \beta_{32}^C = \beta_{33}^C = 0$$

Comparing Model 4 with Model 2 (cont.)

The test uses the *F*-statistic

$$F = \frac{(SS_{Res}(Model \ 2) - SS_{Res}(Model \ 4))/r}{SS_{Res}(Model \ 4)/(n-p)}$$

- r = 3 (the number of parameters set to zero by the null hypothesis)
- n-p=n-6, as there are six parameters in Model 4.

The result on line 140 indicates that the null hypothesis is not rejected, so Model 2 is an adequate simplification of Model 4 (p = 0.4838).

27

Model 5

Fit Model 5:

$$X_2 + X_3$$

that is,

$$Y_i = \beta_{\mathsf{O}} + \sum_{i=1}^{M_2-1} \beta_{2j}^{\scriptscriptstyle{\mathrm{C}}} \mathbb{1}_j(x_{i2}) + \sum_{l=1}^{M_3-1} \beta_{3l}^{\scriptscriptstyle{\mathrm{C}}} \mathbb{1}_l(x_{i3}) + \epsilon_i$$

or

tool+oil.

Model 5 (cont.)

> fit5<-lm(y~tool+oil,data=Tools) > summary(fit.5)

Residual standard error: 4.902 on 15 degrees of freedom Multiple R-squared: 0.7711, Adjusted R-squared: 0.7101 F-statistic: 12.63 on 4 and 15 DF, p-value: 0.0001068

Model 5 (cont.)

The model fitted for $\mathbb{E}_{Y_i|X_i}[Y_i|\mathbf{x}_i]$ is

$$eta_0$$
 $x_{i2} = 0, x_{i3} = 0$ (Type A, Oil 1)
 $eta_0 + eta_{31}^{\text{C}}$ $x_{i2} = 0, x_{i3} = 1$ (Type A, Oil 2)
 $eta_0 + eta_{32}^{\text{C}}$ $x_{i2} = 0, x_{i3} = 2$ (Type A, Oil 3)
 $eta_0 + eta_{33}^{\text{C}}$ $x_{i2} = 0, x_{i3} = 3$ (Type A, Oil 4)
 $eta_0 + eta_{21}^{\text{C}}$ $x_{i2} = 1, x_{i3} = 0$ (Type B, Oil 1)
 $eta_0 + eta_{21}^{\text{C}} + eta_{31}^{\text{C}}$ $x_{i2} = 1, x_{i3} = 1$ (Type B, Oil 2)
 $eta_0 + eta_{21}^{\text{C}} + eta_{32}^{\text{C}}$ $x_{i2} = 1, x_{i3} = 2$ (Type B, Oil 3)
 $eta_0 + eta_{21}^{\text{C}} + eta_{33}^{\text{C}}$ $x_{i2} = 1, x_{i3} = 3$ (Type B, Oil 4)

There are eight subgroups of data defined by the $M_2 \times M_3 = 2 \times 4$ combinations of factor levels. There are five parameters in total, including the intercept β_0 .

Model 5 (cont.)

- The parameter β_{21}^{C} measures the difference in the **intercept** between the Type A and Type B tools, for every Oil type.
- The parameters β^c₃₁, β^c₃₃, β^c₃₃ measure the difference in the intercepts between Oil Types 2, 3 and 4 and Oil Type 1.

Lines 145 - 149 give inference and testing details for

$$\beta_0, \beta_{21}^{\text{C}}, \beta_{31}^{\text{C}}, \beta_{32}^{\text{C}}, \beta_{33}^{\text{C}}$$

respectively.

31

Model 5 (cont.)

Model 5 (cont.)

30

The order of fitting again makes a difference to the sums of squares decomposition. This is because the design is *unbalanced*: there are different numbers of observations in the eight factor level combinations.

```
> table(Tools$tool,Tools$oil)
    1 2 3 4
A 3 3 2 2
```

33

Model 5 (cont.)

Note that dropping the single term oil removes three parameters: all contrasts corresponding to that variable are omitted.

BALANCED DESIGNS

Example: Two factor design

- Factor A: 3 levels, labelled j = 1, 2, 3;
- Factor B: 5 levels, labelled l = 1, 2, 3, 4, 5;
- $n_{il} = 4$ replicate observations for each factor level combination;
- total sample size $n = 3 \times 5 \times 4 = 60$.

We fit the full factorial model

$$A*B = A + B + A:B$$

Example: Two factor design (cont.)

In this model, there is a different assumed mean response for each of the 3×5 factor level combinations; if x_{iA} and x_{iB} represent the indicators of levels for factors A and B, the modelled mean is

$$\beta_0 + \sum_{j=1}^2 \beta_{Aj}^{\text{C}} \mathbb{1}_j(x_{iA}) + \sum_{l=1}^4 \beta_{Bj}^{\text{C}} \mathbb{1}_j(x_{iB}) + \sum_{j=1}^2 \sum_{l=1}^4 \beta_{ABjl}^{\text{C}} \mathbb{1}_j(x_{iA}) \mathbb{1}_l(x_{iB})$$

36

Example: Two factor design (cont.)

In the balanced case, the order in which the factors are included in the model does not change the sum of squares decomposition, or the assessment of statistical significance.

For example in assessing the significance of the interaction term A:B, we obtain the same test result from the two anova calculations as from drop1: see lines 37, 49 and 60.
